
Botany Bouquet

Activity Overview

A warm-up activity to introduce various plant species from the same or different ecosystems which encourages observational, organizational, and taxonomic skills.

Objectives

Students will:

- Use their observational skills
- Learn how plants differ structurally from one another
- Increase their understanding of plant diversity

Subjects Covered

Science and Language Arts

Grades

1 through 12

Activity Time

30-45 minutes

Season

Any

Materials

Sample plant cuttings from the same (or different ecosystems) that are representative of the native garden(s) you have planted (or plan to plant) on your school grounds.

State Standards

Science:

Language Arts:

*Adapted to California by Return of the Natives•CSU Monterey Bay

Background

There are a variety of languages spoken around the world. In North America, you can find many different languages, ranging from English, Hmong, and French to Spanish, German, and indigenous languages like Cayuga and Oneida languages, among others. Most of the words found in European languages are based on words used by the early Greeks and Romans.

Scientific names are basically another language system, which uses Latin as the root source. Latin, which is often a combination of Latin and Greek, was historically the language used by educated people, which is typically understood to be the reason why Latin was chosen to give scientific names to plants and animals.

For a long time scientists were confronted with the challenge that one plant or animal species could have many different names, depending what language you spoke. This challenge created all sorts of language barriers when scientists from different parts of the world wanted to talk about their research. In 1758, a Swedish biologist, Carl Linnaeus, decided everyone should use the same name to describe a given species and proposed a universal naming system. Now known as “binomial nomenclature” (bi = two, nomen = name, calo = call, so it translates as “two-name name-calling”), this naming system gives each species a surname and a personal name, just like people in the North America have. If you are called Pat Jones then Jones is your surname, and Pat is your personal name.

Scientists call the equivalent of a person’s last name the “genus” or “generic name.” The genus always has a capital letter as the first letter. The equivalent of a person’s first name is called the “specific name” and is written entirely in lower case letters. Unlike people’s names in North America, the generic name comes first and the personal (specific) name is second in this binomial system. The scientific name is either italicized or underlined so you can tell it is a specific life form. For example, the Latin name for the tree species, scrub oak, is *Quercus dumosa*. *Quercus* is the family name, and there are several different types of oak trees in California that have the same first name. This is just like how you and your siblings would have the same last name. The species name, *agrifolia*, is similar to your first name and tells you it is a scrub oak.

These Latin names have other meanings, too. For instance, “*dumosa*” means “a bramble, bushy, thorny” in Latin, which describes how this oak looks. The same used to be true for people’s names, too. For instance, people with the last name, White, could have had a baker or flour miller in their family history who was always covered in white flour. The same is true with scientific names, which either describe the plant or animal, or tell you who first gave the species that name. Another convention in the binomial nomenclature is that the first time a Long Beech Fern

Botany Bouquet (cont.)

(*Dryopteris phegopteris*) species name is written, the full scientific Latin name is written out. The next time this species is written, the genus name is shortened to just the first letter with a period after it. For example, *Quercus dumosa* could now be shortened to *Q. dumosa* because the species has already been mentioned by its full name in this document.

The following activity will help students understand the scientific naming process and familiarize them with the diversity of the ecosystem they want to restore on their school grounds. The natural world is bursting with a diversity of plants and animals that have evolved living closely together in their natural habitat. The presence of enough plant and animal diversity better ensures that some of them will withstand potential disturbances in nature, ranging from floods and drought to disease and fire, among others. Diverse ecosystems are more likely to include plants that can tolerate such stressors. Maintaining the diversity of different ecosystems is one indication of the importance of ecological restorations and protecting species. Keep in mind that it is not necessary to know the names of all the native plants to create a school restoration site. Learning plant names comes slowly. This activity is one way to become familiar with plant diversity. Students learn the variety of patterns and shapes of plant parts. The next step can be putting names to what they observe in terms of plant structure (see Earth Partnership for Schools activity, "Plant Families").

In addition to acquainting students with ecological diversity and species names, this activity is a good introductory activity to a plant unit and/or can be used as an "ice-breaker" among a group of students who do not know each other well. Likewise, this activity can sharpen participants' observation skills and build upon their creativity as they learn more about plant structure and diversity.

Activity Description

1. Prepare a bouquet of plant species, representing one or more ecosystems. The number of sample plants will depend on the size of the group and should be approximately a third to a quarter of the number in the group. For example, a group of 30 students will break into 6 groups of five, which will require five samples from 6 different plant species.
2. Have the bouquet well mixed and pass out one plant to each person.
3. Ask those who know names of the plants being passed out to not share that information until the end of the activity.
4. Allow group members to find others who have the same plant and then form a small group. If participants do not know one another, instruct them to introduce themselves to the other group members.
5. Ask groups to come up with a creative description of the plant based on their close observations that would help others identify that plant.
6. Then, ask them to come up with a creative name for their plant.
7. At this point, have representative(s) from each group present their plant's name and description.
8. Once a small group has shared their creative name and related plant description, ask the entire group if they know what the common and scientific name of the plant. If the name is un-

known, share common and Latin names, and a further description (especially ecological and human uses) of each plant.

Discussion

Ask group members why they think there are scientific names for plants, then review the history of why plants have scientific and common names. Have students visit the library to further research the plants used during this activity, the related habitat preferences, and human uses for the plants. Also, encourage them to expand on this activity to include different plant and animals that would be found in the habitat they are restoring on their school grounds.

Extensions

- Complete Earth Partnership for Schools activity, “Plant Families,” to learn more about plant structure and identification.
- Collect other plant samples and complete this activity with additional plants representing either the same or different ecosystem.
- Write a story that describes a plant and its characteristics and explains the related adaptations.
- Keep a phenology journal and record plant changes during different times of year (see Earth Partnership for Schools Activities, “Observations from a Single Spot”).
- Create a phenology calendar that describes your plant observations throughout the year.
- Create a computer database to record seasonal observations of plants found in your school restoration site.

Assessments

- Name (common and scientific name) and describe at least 2 plant species.
- Write a short story describing the plant species used in this activity, the human uses of the plant (e.g., medicinal uses), and the root words of the plant's scientific name.
- Create a mobile with drawings illustrating various plants and their unique physical characteristics. Include the scientific and common names on the mobile.
- Research a plant species; describe its characteristics, habitat where the species is most likely to be found, and common human uses. Make an oral report to the class and conduct peer reviews of these reports.
- Students develop a web page on the plant species from this activity using photos, drawings, and life history information.
- Students conduct research in their restoration site related to the plants identified and record observations for a specific time frame.
